

Download File PDF Operation Management An Asian Perspective Answer Key

#Jenny

Finally I get this ebook, thanks for all these I can get now!

#Rio

Cool! I'am really happy

#Markus Jensen

I did not think that this would work, my best friend showed me this website, and it does! I get my most wanted eBook

#Hun Tsu

wtf this great ebook for free?!

#Che Salsa

My friends are so mad that they do not know how I have all the high quality ebook which they do not!

#Diego Butler

so many fake sites. this is the first one which worked! Many thanks

167 CHAPTER 12 MANAGING INVENTORY

- 1218 (a) Reorder point = Demand during lead time
= 100 units/day \times 2.5 days = 250 units
(b) Demand during lead time (daily) = 200 units/day
ROP = 200 units/day \times 2.5 days = 500 units
(c) Demand during lead time (daily) = 200 units/day
ROP = 200 units/day \times 2.5 days = 500 units
- 1219 (a) $Q = 1000$
Number of orders per year = 360
Lead time = 5 days
ROP = (Demand/Day) \times (Lead time) = (10,000/300) \times 5 = 166.67 units
(b) This number is important because it helps Decision Key enough inventory to prevent stockouts while she waits for the new order to arrive.
- 1220 (a) $EOQ = \sqrt{\frac{2 \times \text{Annual Demand} \times \text{Order Cost}}{\text{Unit Cost}}}$
 $= \sqrt{\frac{2 \times 100,000 \times 10}{100}} = 141.42$ units
(b) Average inventory = 70.71 units
(c) Optimal number of orders per year = 2.57
(d) Optimal days between orders = 7.91
(e) Cost of inventory management, excluding cost of goods = (11.62 \times 200) + (16.67 \times 100) = \$4,000
(f) Total annual inventory cost = \$41,875.00 (including the \$40,000 cost of goods)
Now, Reorder point is arrived.
- 1221 (a) $Q = \sqrt{\frac{2 \times \text{Annual Demand} \times \text{Order Cost}}{\text{Unit Cost}}}$
 $= \sqrt{\frac{2 \times 100,000 \times 10}{100}} = 141.42$ units
(b) Average inventory = 70.71 units
(c) Annual holding cost = $\frac{Q}{2} \times \text{Unit Cost} = \frac{141.42}{2} \times 100 = \$7,071$
(d) Annual order cost = $\frac{D}{Q} \times \text{Order Cost} = \frac{100,000}{141.42} \times 10 = \707.1
(e) $TC = \frac{D}{Q} \times \text{Order Cost} + \frac{Q}{2} \times \text{Unit Cost} = 707.1 + 7,071 = \$7,778.1$
(f) Time between orders = $\frac{360 \text{ days}}{\text{Number of orders per year}} = \frac{360}{2.57} = 139.7$ days
(g) ROP = $d \times L = 100 \times 2 = 20$ units (where 10 = daily demand)
- 1224 (a) Total cost = Order cost + Holding cost = $\frac{D}{Q} \times C_o + \frac{Q}{2} \times C_h$
For $Q = 25$: $\frac{1,200 \times 25}{25} + \frac{25 \times 25}{2} = \$1,200$
For $Q = 50$: $\frac{1,200 \times 25}{50} + \frac{50 \times 25}{2} = \$1,250$
For $Q = 100$: $\frac{1,200 \times 25}{100} + \frac{100 \times 25}{2} = \$1,250$
For $Q = 200$: $\frac{1,200 \times 25}{200} + \frac{200 \times 25}{2} = \$1,250$
For $Q = 400$: $\frac{1,200 \times 25}{400} + \frac{400 \times 25}{2} = \$1,500$
(b) Economic Order Quantity:
 $Q^* = \sqrt{\frac{2 \times D \times C_o}{C_h}} = \sqrt{\frac{2 \times 1,200 \times 25}{25}} = 50$ units
where D = annual demand, S = setup or order cost, C_h = holding cost per unit per year.
As expected, total cost varies as order quantity will not have a significant effect on total cost. If we order twice as many (e.g., Q goes from 25 to 50), TC increases by only \$500 (see part a).
- 1225 (a) The EOQ assumptions are met, so the optimal order quantity is:
 $EOQ = \sqrt{\frac{2 \times \text{Annual Demand} \times \text{Order Cost}}{\text{Unit Cost}}}$
 $= \sqrt{\frac{2 \times 100,000 \times 10}{100}} = 141.42$ units
(b) Number of orders per year = $D/Q = 100,000/141.42 = 707.1$ orders per year.
Note that this would mean in one year the company places 707 orders and in the next it would only need 2 orders since sales inventory would be carried over from the previous year. It averages 2.5 orders per year.
(c) Average inventory = $Q/2 = 100,000/2 = 50$ units
(d) Given an annual demand of 200, a carrying cost of \$5, and an order quantity of 100, Franco's Electronics must determine what the ordering cost would have to be for the order policy of 100 units to be optimal. To find the answer to the problem, we must solve the traditional economic order quantity equation for the ordering cost. As you can see in the calculation, an ordering cost of \$45 is needed for the order quantity of 100 units to be optimal.
